Interactions in Logistic Regression

Andy Grogan-Kaylor

7 Jul 2020

Background

The purpose of this tutorial is to illustrate the idea that in *logistic regression*, the β parameter for an interaction term may not accurately characterize the underlying interactive relationships.

This idea may be easier to describe if we recall the formula for a logistic regression:

$$\ln\left(\frac{P(y)}{1 - P(y)}\right) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1 * x_2$$

In the above formula, the sign, and statistical significance, of β_3 may not accurately characterize the underlying relationship.

Get The Data

We start by obtaining *simulated data* from StataCorp.

- . clear all
- . graph close _all
- . use http://www.stata-press.com/data/r15/margex, clear
 (Artificial data for margins)

Describe The Data

The variables are as follows:

. describe

Estimate Logistic Regression

We then run a logistic regression model in which outcome is the dependent variable. sex, age and group are the independent variables. We estimate an interaction of sex and age.

We note that the regression coefficient for the interaction term is not statistically significant.

```

Plotting Margins

margins provides a lot of results, which can be difficult to understand. Therefore, we use marginsplot to plot these margins results. The key command is marginsplot, which could be used on its own. I have simply added the Michigan graph scheme, as well as some options to improve the graphic design of the plot.

There certainly seems to be some kind of interaction of sex and age.

```
. marginsplot, ///
> scheme(michigan) /// michigan graph scheme
> plotopts(msize(vlarge)) /// larger plotting symbols
> plot1opts(lcolor(navy)) /// line for first group is navy
> plot2opts(lcolor(gold)) // line for second group is gold
    Variables that uniquely identify margins: age sex
. graph export mymarginsplot.png, width(500) replace
(file mymarginsplot.png written in PNG format)
```

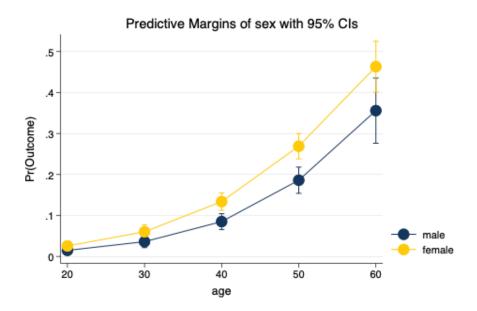

Figure 1: Margins Plot

Rerun margins, Posting Results

We again employ the margins command, this time using the post option so that the results of the margins command are *posted* as an estimation result. This will allow us to employ the test command to statistically test different margins against each other.

Testing Margins Against Each Other

Lastly, we test the margins at age 20 for men and women, and again at age 60 for men and women.

We note that the original regression parameter for the interaction term was not statistically significant. Indeed, the margins at age 20 are not statistically significantly different by sex. However, at age 60, there is a statistically significant difference by sex.
